Genome Enhancer release 3.3 (TRANSFAC®, TRANSPATH® and HumanPSD™ release 2023.2)

### **Abstract**

In the present study we applied the software package "Genome Enhancer" to a data set that contains *epigenomics* data. The study is done in the context of *Hypertension*. The goal of this pipeline is to identify potential drug targets in the molecular network that governs the studied pathological process. In the first step of analysis pipeline discovers transcription factors (TFs) that regulate genes activities in the pathological state. The activities of these TFs are controlled by so-called master regulators, which are identified in the second step of analysis. After a subsequent druggability checkup, the most promising master regulators are chosen as potential drug targets for the analyzed pathology. At the end the pipeline comes up with (a) a list of known drugs and (b) investigational active chemical compounds with the potential to interact with selected drug targets.

From the data set analyzed in this study, we found the following TFs to be potentially involved in the regulation of the highly methylated genes: BCL6, ZBTB7B and ZNF462. The subsequent network analysis suggested

- RSK
- FAM123B
- trkC
- MKP-4
- AR-isoform1

as the most promising molecular targets for further research, drug development and drug repurposing initiatives on the basis of identified molecular mechanism of the studied pathology. Having checked the actual druggability potential of the full list of identified targets, both, via information available in medical literature and via cheminformatics analysis of drug compounds, we have identified the following drugs as the most promising treatment candidates for the studied pathology: Imatinib, Flavopiridol, Moexipril and 2,5,7-Trihydroxynaphthoquinone.

### 1. Introduction

Recording "-omics" data to measure gene activities, protein expression or metabolic events is becoming a standard approach to characterize the pathological state of an affected organism or tissue. Increasingly, several of these methods are applied in a combined approach leading to large "multiomics" datasets. Still the challenge remains how to reveal the underlying molecular mechanisms that render a given pathological state different from the norm. The disease-causing mechanism can be described by a re-wiring of the cellular regulatory network, for instance as a result of a genetic or epigenetic alterations influencing the activity of relevant genes. Reconstruction of the disease-specific regulatory networks can help identify potential master regulators of the respective pathological process. Knowledge about these master regulators can point to ways how to block a pathological regulatory cascade. Suppression of certain molecular targets as components of these cascades may stop the pathological process and cure the disease.

Conventional approaches of statistical "-omics" data analysis provide only very limited information about the causes of the observed phenomena and therefore contribute little to the understanding of the pathological molecular mechanism. In contrast, the "upstream analysis" method [1-4] applied here has been deviced to provide a casual interpretation of the data obtained for a pathology state. This approach comprises two major steps: (1) analysing promoters and enhancers of highly methylated genes for the transcription factors (TFs) involved in their regulation and, thus, important for the process under study; (2) re-constructing the signaling pathways that activate these TFs and identifying master regulators at the top of such pathways. For the first step, the database TRANSFAC® [6] is employed together with the TF binding site identification algorithms Match [7] and CMA [8]. The second step involves the signal transduction database TRANSPATH® [9] and special graph search algorithms [10] implemented in the software "Genome Enhancer".

The "upstream analysis" approach has now been extended by a third step that reveals known drugs suitable to inhibit (or activate) the identified molecular targets in the context of the disease under study. This step is performed by using information from HumanPSD<sup>TM</sup> database [5]. In addition, some known drugs and investigational active chemical compounds are subsequently predicted as potential ligands for the revealed molecular targets. They are predicted using a pre-computed database of spectra of biological activities of chemical compounds of a library of 2245 known drugs and investigational chemical compounds from HumanPSD<sup>TM</sup> database. The spectra of biological activities for these compounds are computed using the program PASS on the basis of a (Q)SAR approach [11-13]. These predictions can be used for the research purposes - for further drug development and drug repurposing initiatives.

# 2. Data

For this study the following experimental data was used:

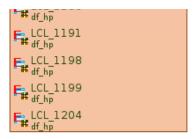

Figure 1. Annotation diagram of experimental data used in this study. With the colored boxes we show those sub-categories of the data that are compared in our analysis.

# 3. Results

We have compared the following conditions: Hypertension versus Control.

# 3.1. Identification of target genes

In the first step of the analysis *target genes* were identified from the uploaded experimental data. The most highly methylated genes were used as target genes.

Table 2. Top ten highly methylated genes in Hypertension vs. Control.

# 3.2. Functional classification of genes

A functional analysis of highly methylated genes was done by mapping the genes to several known ontologies, such as Gene Ontology (GO), disease ontology (based on HumanPSD<sup>TM</sup> database) and the ontology of signal transduction and metabolic pathways from the

TRANSPATH® database. Statistical significance was computed using a binomial test. Figures 2-4 show the most significant categories.

# Highly methylated genes in Hypertension vs. Control:

300 top methylated genes were taken for the mapping.

Full classification -

The result of overall Gene Ontology (GO) analysis of the highly methylated genes of the studied pathology can be summarized by the following diagram, revealing the most significant functional categories overrepresented among the observed (highly methylated genes):

- Highly methylated genes in Hypertension vs. Control hits
- Highly methylated genes in Hypertension vs. Control -log10(P-value)

# 3.3. Analysis of enriched transcription factor binding sites and composite modules

In the next step a search for transcription factors binding sites (TFBS) was performed in the regulatory regions of the *target genes* by using the TF binding motif library of the TRANSFAC® database. We searched for so called **composite modules** that act as potential condition-specific **enhancers** of the *target genes* in their upstream regulatory regions (-1000 bp upstream of transcription start site (TSS)) and identify transcription factors regulating activity of the genes through such **enhancers**.

Classically, **enhancers** are defined as regions in the genome that increase transcription of one or several genes when inserted in either orientation at various distances upstream or downstream of the gene [8]. Enhancers typically have a length of several hundreds of nucleotides and are bound by multiple transcription factors in a cooperative manner [9].

In the current work we use the Epigenomics data from the track(s) "Methylation track" to predict positions of potential *enhancers* regulating the highly methylated genes revealed by comparative epigenomics analysis. We took genomic regions -550bp upstream and 550bp downstream from the middle point of each interval of the track and check if these regions are located inside the 5kb flanking areas of the highly methylated genes (or inside the body of the genes). In such cases, these genomic regions are used for the search for potential condition-specific enhancers. In all other cases when the differentially expressed genes did not contain epigenomic peaks in their body or in the 5kb flanking regions we used the upstream regulatory regions of these genes (-1000bp upstream and 100bp downstream of TSS) for the search for condition-specific enhancers.

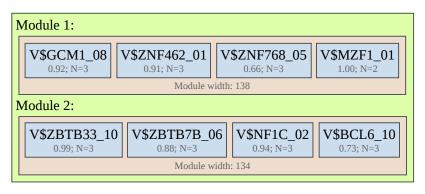

We applied the Composite Module Analyst (CMA) [8] method to detect such potential enhancers, as targets of multiple TFs bound in a cooperative manner to the regulatory regions of the genes of interest. CMA applies a genetic algorithm to construct a generalized model of the enhancers by specifying combinations of TF motifs (from TRANSFAC®) whose sites are most frequently clustered together in the regulatory regions of the studied genes. CMA identifies the transcription factors that through their cooperation provide a synergistic effect and thus have a great influence on the gene regulation process.

# Enhancer model potentially involved in regulation of target genes (highly methylated genes in Hypertension vs. Control).

To build the most specific composite modules we choose top methylated genes as the input of CMA algorithm. The obtained CMA model is then applied to compute CMA score for all highly methylated genes in Hypertension vs. Control.

The model consists of 2 module(s). Below, for each module the following information is shown:

- PWMs producing matches,
- number of individual matches for each PWM,
- score of the best match.

Model score (-p\*log10(pval)): 30.55 Wilcoxon p-value (pval): 9.67e-58

Penalty (p): 0.536

Average yes-set score: 10.31 Average no-set score: 8.60

**AUC:** 0.74

Separation point: 9.47 False-positive: 31.33% False-negative: 31.93%

 $The \ AUC \ of the \ model \ achieves \ value \ significantly \ higher \ than \ expected \ for \ a \ random \ set \ of \ regulatory \ regions$ 

Z-score = 3.06

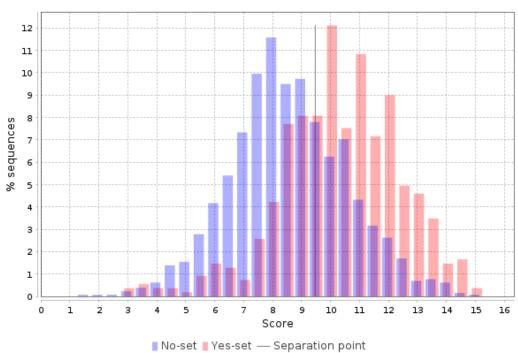

Table 3. List of top ten highly methylated genes in Hypertension vs. Control with identified enhancers in their regulatory regions. **CMA score** - the score of the CMA model of the enhancer identified in the regulatory region.

On the basis of the enhancer models we identified transcription factors potentially regulating the *target genes* of our interest. We found 8 transcription factors controlling expression of highly methylated genes in Hypertension vs. Control (see Table 4).

Table 4. Transcription factors of the predicted enhancer model potentially regulating the highly methylated genes (highly methylated genes in Hypertension vs. Control). **Yes-No ratio** is the ratio between frequencies of the sites in Yes sequences versus No sequences. It describes the level of the enrichment of binding sites for the indicated TF in the regulatory target regions. **Regulatory score** is the measure of involvement of the given TF in the controlling of expression of genes that encode master regulators presented below (through positive feedback loops).

**See full table** →

ID	Gene symbol	Gene description	Regulatory score	Yes-No ratio

The following diagram represents the key transcription factors, which were predicted to be potentially regulating highly methylated genes in the analyzed pathology: BCL6, ZBTB7B and ZNF462.

# 3.4. Finding master regulators in networks

In the second step of the upstream analysis common regulators of the revealed TFs were identified. These master regulators appear to be the key candidates for therapeutic targets as they have a master effect on regulation of intracellular pathways that activate the pathological process of our study. The identified master regulators are shown in Table 5.

Table 5. Master regulators that may govern the regulation of highly methylated genes in Hypertension vs. Control. **Total rank** is the sum of the ranks of the master molecules sorted by keynode score, CMA score, epigenomics data.

×	00	 tab	10	
	-	 tab		_

ID	Master molecule name	Gene symbol	Gene description	Total rank

The intracellular regulatory pathways controlled by the above-mentioned master regulators are depicted in Figure 5. This diagram displays the connections between identified transcription factors, which play important roles in the regulation of highly methylated genes, and selected master regulators, which are responsible for the regulation of these TFs.

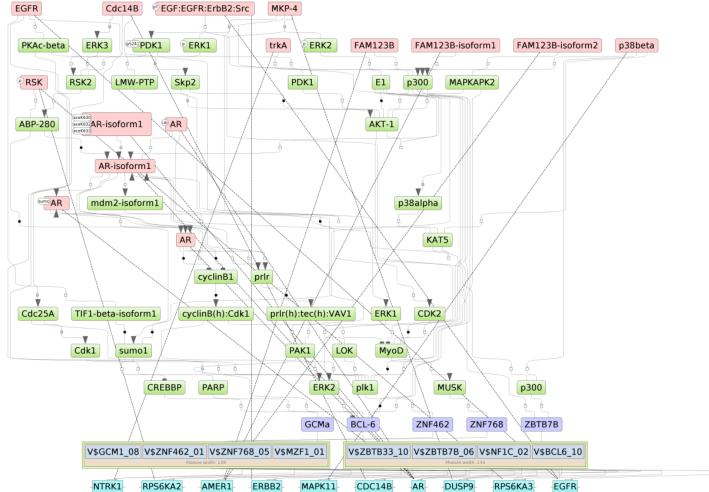

Figure 5. Diagram of intracellular regulatory signal transduction pathways of highly methylated genes in Hypertension vs. Control. Master regulators are indicated by red rectangles, transcription factors are blue rectangles, and green rectangles are intermediate molecules, which have been added to the network during the search for master regulators from selected TFs.

See full diagram 

The properties of transcription pathways of highly methylated genes in Hypertension vs. Control. Master regulators are indicated by red rectangles, transcription factors are blue rectangles, and green rectangles are intermediate molecules, which have been added to the network during the search for master regulators from selected TFs.

# 4. Finding prospective drug targets

The identified master regulators that may govern pathology associated genes were checked for druggability potential using HumanPSD<sup>TM</sup> [5] database of gene-disease-drug assignments and PASS [11-13] software for prediction of biological activities of chemical compounds on the basis of a (Q)SAR approach. Respectively, for each master regulator protein we have computed two Druggability scores: HumanPSD Druggability score and PASS Druggability score. Where Druggability score represents the number of drugs that are potentially suitable for inhibition (or activation) of the corresponding target either according to the information extracted from medical literature (from HumanPSD<sup>TM</sup> database) or according to cheminformatics predictions of compounds activity against the examined target (from PASS software).

The cheminformatics druggability check is done using a pre-computed database of spectra of biological activities of chemical compounds from a library of all small molecular drugs from HumanPSD $^{\text{TM}}$  database, 2507 pharmaceutically active known chemical compounds in total. The spectra of biological activities has been computed using the program PASS [11-13] on the basis of a (Q)SAR approach.

If both Druggability scores were below defined thresholds (see Methods section for the details) such master regulator proteins were not used in further analysis of drug prediction.

As a result we created the following two tables of prospective drug targets (top targets are shown here):

Table 6. Prospective drug targets selected from full list of identified master regulators filtered by Druggability score from HumanPSD™ database. Druggability score contains the number of drugs that are potentially suitable for inhibition (or activation) of the target. The drug targets are sorted according to the Total rank which is the sum of three ranks computed on the basis of the three scores: keynode score, CMA score and expression change score (logFC, if present). See Methods section for details.

### See full table

Gene symbol	Gene Description	<b>Druggability score</b>	<b>Total rank</b>
AR	androgen receptor	78	60
NTRK3	neurotrophic receptor tyrosine kinase 3	34	155
EPHA8	EPH receptor A8	29	173
TSC22D3	TSC22 domain family member 3	3	241
TSPYL2	TSPY like 2	1	263
ALK	ALK receptor tyrosine kinase	42	275

details.

Table 7. Prospective drug targets selected from full list of identified master regulators filtered by Druggability score predicted by PASS software. Here, the Druggability score for master regulator proteins is computed as a sum of PASS calculated probabilities to be active as a target for various small molecular compounds. The drug targets are sorted according to the Total rank which is the sum of three ranks computed on the basis of the three scores: keynode score, CMA score and expression change score (logFC, if present). See Methods section for

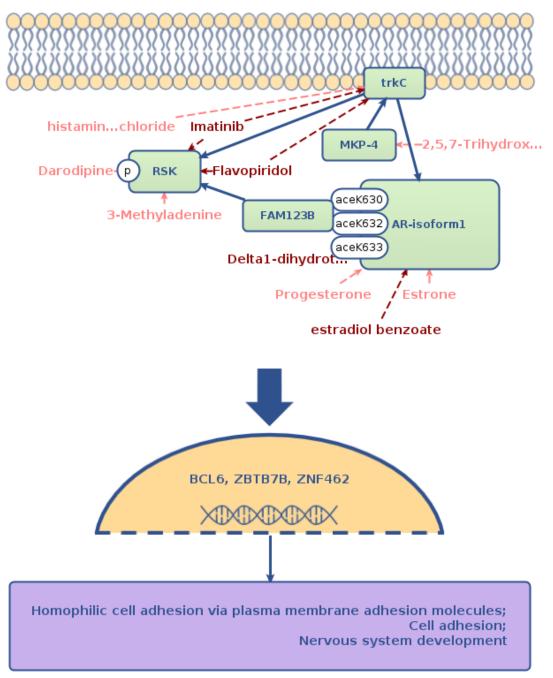

### See full table →

Gene symbol	Gene Description	Druggability score	Total rank
DUSP9	dual specificity phosphatase 9	35.02	45
AR	androgen receptor	11.8	60
NTRK3	neurotrophic receptor tyrosine kinase 3	9.41	155
EPHA8	EPH receptor A8	17.52	173
ALK	ALK receptor tyrosine kinase	10.66	275
NTF3	neurotrophin 3	17.39	277

Below we represent schematically the main mechanism of the studied pathology. In the schema we considered the top two drug targets of each of the two categories computed above. In addition we have added two top identified master regulators for which no drugs may be identified yet, but that are playing the crucial role in the molecular mechanism of the studied pathology. Thus the molecular mechanism of the studied pathology was predicted to be mainly based on the following key master regulators:

- RSK
- FAM123B
- trkC
- MKP-4
- AR-isoform1

This result allows us to suggest the following schema of affecting the molecular mechanism of the studied pathology:

Drugs which are shown on this schema: estradiol benzoate, 2,5,7-Trihydroxynaphthoquinone, Imatinib, Delta1-dihydrotestosterone, Flavopiridol, Darodipine, Estrone, Progesterone, histamine dihydrochloride and 3-Methyladenine, should be considered as a prospective research initiative for further drug repurposing and drug development. These drugs were selected as top matching treatments to the most prospective drug targets of the studied pathology, however, these results should be considered with special caution and are to be used for research purposes only, as there is not enough clinical information for adapting these results towards immediate treatment of patients.

The drugs given in dark red color on the schema are FDA approved drugs or drugs which have gone through various phases of clinical trials as active treatments against the selected targets.

The drugs given in pink color on the schema are drugs, which were cheminformatically predicted to be active against the selected targets.

# 5. Identification of potential drugs

In the last step of the analysis we strived to identify known activities as well as drugs with cheminformatically predicted activities that are potentially suitable for inhibition (or activation) of the identified molecular targets in the context of specified human diseases(s).

Proposed drugs are top ranked drug candidates, that were found to be active on the identified targets and were selected from 4 categories:

- 1. FDA approved drugs or used in clinical trials drugs for the studied pathology;
- 2. Repurposing drugs used in clinical trials for other pathologies;
- 3. Drugs, predicted by PASS to be active against identified drug targets and against the studied pathology;
- 4. Drugs, predicted by PASS to be active against identified drug targets but for other pathologies.

Proposed drugs were selected on the basis of Drug rank which was computed from the ranks sum based on the individual ranks of the following scores:

- Target activity score (depends on ranks of all targets that were found for the selected drug);
- Disease activity score (weighted sum of number of clinical trials on disease(s) under study where the selected drug is known to be applied or PASS Disease activity score cheminformatically predicted property of the compound to be active against the studied disease(s));
- Clinical validity score (applicable only for drugs predicted on the basis of literature curation in HumanPSD™ database (Tables 8 and 9), reflects the number of the highest clinical trials phase on which the drug was tested for any pathology).

You can refer to the Methods section for more details on drug ranking procedure.

Based on the Drug rank, a numerical value of Drug score was calculated, which reflects the potential activity of the respective drug on the overall molecular mechanism of the studied pathology. Drug score values belong to the range from 1 to 100 and are calculated as a quotient of maximum drug rank and the drug rank of the given drug multiplied by 100.

Top drugs of each category are given in the tables below:

# **Drugs approved in clinical trials**

RPS6KA2, MAPK4,

[[N- (Benzyloxycarbonyl)Amino]Methyl]Phosphate	PTPRR, ACE2, GRIN1, DUSP22, PTPRO, PTPRF, PTPN2, PTPN13, PTPRH, CDC14B, DUSP14, DUPD1, DUSP9, PTPN21	84	0.49
histamine dihydrochloride	BMX, LCK, MAPK10, ALK, EPHB2, NTRK1, NTRK3, MAPK4, KDR, ERBB4, INSRR, FLT4, INSR, LTK, EGFR, BTK, EPHA6, MAPK11, ERBB2, FYN, EPHA8, RET, ABL2, IGF1R	84	1.21
Fenoldopam	MAPK10, GRIN1, MAPK4, MAPK11	82	0.14

As the result of drug search we propose the following drugs as most promising candidates for treating the pathology under study: Imatinib, Flavopiridol, Moexipril and 2,5,7-Trihydroxynaphthoquinone. These drugs were selected for acting on the following targets: NTRK3, NTF3 and DUSP9, which were predicted to be active in the molecular mechanism of the studied pathology.

The selected drugs are top ranked drug candidates from each of the four categories of drugs: (1) FDA approved drugs or used in clinical trials drugs for the studied pathology; (2) repurposing drugs used in clinical trials for other pathologies; (3) drugs, predicted by PASS software to be active against the studied pathology; (4) drugs, predicted by PASS software to be repurposed from other pathologies.

### 6. Conclusion

We applied the software package "Genome Enhancer" to a data set that contains *epigenomics* data. The study is done in the context of *Hypertension*. The data were pre-processed, statistically analyzed and highly methylated genes were identified. Also checked was the enrichment of GO or disease categories among the studied gene sets.

We propose the following drugs as most promising candidates for treating the pathology under study:

Imatinib, Flavopiridol, Moexipril and 2,5,7-Trihydroxynaphthoquinone

These drugs were selected for acting on the following targets: NTRK3, NTF3 and DUSP9, which were predicted to be involved in the molecular mechanism of the pathology under study.

The identified molecular mechanism of the studied pathology was predicted to be mainly based on the following key drug targets:

RSK, FAM123B, trkC, MKP-4 and AR-isoform1

These potential drug targets should be considered as a prospective research initiative for further drug repurposing and drug development purposes. The following drugs were predicted as, matching those drug targets: estradiol benzoate, 2,5,7-Trihydroxynaphthoquinone, Imatinib, Delta1-dihydrotestosterone, Flavopiridol, Darodipine, Estrone, Progesterone, histamine dihydrochloride and 3-Methyladenine. These drugs should be considered with special caution for research purposes only.

In this study, we came up with a detailed signal transduction network regulating highly methylated genes in the studied pathology. In this network we have revealed the following top master regulators (signaling proteins and their complexes) that play a crucial role in the molecular mechanism of the studied pathology, which can be proposed as the most promising molecular targets for further drug repurposing and drug development initiatives.

- RSK
- FAM123B
- trkC
- MKP-4
- AR-isoform1

Potential drug compounds which can be affecting these targets can be found in the "Finding prospective drug targets" section.

# 7. Methods

### Databases used in the study

Transcription factor binding sites in promoters and enhancers of highly methylated genes were analyzed using known DNA-binding motifs described in the TRANSFAC® library, release 2023.2 (geneXplain GmbH, Wolfenbüttel, Germany) (https://genexplain.com/transfac).

The master regulator search uses the TRANSPATH® database (BIOBASE), release 2023.2 (geneXplain GmbH, Wolfenbüttel, Germany) (https://genexplain.com/transpath). A comprehensive signal transduction network of human cells is built by the software on the basis of reactions annotated in TRANSPATH®.

The information about drugs corresponding to identified drug targets and clinical trials references were extracted from HumanPSD<sup>TM</sup> database, release 2023.2 (https://genexplain.com/humanpsd).

The Ensembl database release Human104.38 (hg38) (http://www.ensembl.org) was used for gene IDs representation and Gene Ontology (GO) (http://geneontology.org) was used for functional classification of the studied gene set.

### **Epigenomics data processing**

When analyzing a list of CpG sites, we compute the fold change values between the methylation status in the studied pathology and the control set. Top 10 000 CpG sites with highest logFC values are taken to further analysis. These sites are mapped to corresponding genes, which will be further compared to the list of housekeeping genes at the step of promoter analysis.

# Methods for the analysis of enriched transcription factor binding sites and composite modules

Transcription factor binding sites in promoters and enhancers of differentially expressed genes were analyzed using known DNA-binding motifs. The motifs are specified using position weight matrices (PWMs) that give weights to each nucleotide in each position of the DNA binding motif for a transcription factor or a group of them.

We search for transcription factor binding sites (TFBS) that are enriched in the enhancers under study as compared to a background set of promoters of housekeeping genes. We denote study and background sets briefly as Yes and No sets. In the current work we used a workflow considering promoter sequences of a standard length of 1100 bp (-1000 to +100). The error rate in this part of the pipeline is controlled by estimating the adjusted p-value (using the Benjamini-Hochberg procedure) in comparison to the TFBS frequency found in randomly selected regions of the human genome (adj.p-value < 0.01).

We have applied the CMA algorithm (Composite Module Analyst) for searching composite modules [7] in the promoters and enhancers of the Yes and No sets. We searched for a composite module consisting of a cluster of 10 TFs in a sliding window of 200-300 bp that statistically significantly separates sequences in the Yes and No sets (minimizing Wilcoxon p-value).

## Methods for finding master regulators in networks

We searched for master regulator molecules in signal transduction pathways upstream of the identified transcription factors. The master regulator search uses a comprehensive signal transduction network of human cells. The main algorithm of the master regulator search has been described earlier [3,4]. The goal of the algorithm is to find nodes in the global signal transduction network that may potentially regulate the activity of a set of transcription factors found at the previous step of the analysis. Such nodes are considered as most promising drug targets, since any influence on such a node may switch the transcriptional programs of hundreds of genes that are regulated by the respective TFs. In our analysis, we have run the algorithm with a maximum radius of 12 steps upstream of each TF in the input set. The error rate of this algorithm is controlled by applying it 10000 times to randomly generated sets of input transcription factors of the same set-size. Z-score and FDR value of ranks are calculated then for each potential master regulator node on the basis of such random runs (see detailed description in [9]). We control the error rate by the FDR threshold 0.05.

### Methods for analysis of pharmaceutical compounds

We seek for the optimal combination of molecular targets (key elements of the regulatory network of the cell) that potentially interact with pharmaceutical compounds from a library of known drugs and biologically active chemical compounds, using information about known drugs from HumanPSD™ and predicting potential drugs using PASS program.

We selected compounds from HumanPSD™ database that have at least one target. Next, we sort compounds using "*Drug rank*" that is the sum of the following ranks:

- 1. ranking by "Target activity score" (*T-score*<sub>PSD</sub>),
- 2. ranking by "Disease activity score" (*D-score*<sub>PSD</sub>),
- 3. ranking by "Clinical validity score".

"Target activity score" (*T-score*<sub>PSD</sub>) is calculated as follows:

$$T\text{-}score_{\scriptscriptstyle PSD} = -\frac{|T|}{|T| + w(|AT| - |T|))} \sum_{t \in T} log_{10} \left( \frac{rank(t)}{1 + maxRank(T)} \right),$$

where T is set of all targets related to the compound intersected with input list, |T| is number of elements in T, AT and |AT| are set set of all targets related to the compound and number of elements in it, w is weight multiplier, rank(t) is rank of given target, maxRank(T) equals max(rank(t)) for all targets t in T.

We use following formula to calculate "Disease activity score" (D-score<sub>PSD</sub>):

$$D\text{-}score_{\scriptscriptstyle PSD} = \begin{cases} \sum\limits_{d \in D} \sum\limits_{p \in P} phase(d,p) \\ 0, \ D = \varnothing \end{cases},$$

where D is the set of selected diseases, and if D is empty set, D-score<sub>PSD</sub>=0. P is a set of all known phases for each disease, phase(p,d) equals to the phase number if there are known clinical trials for the selected disease on this phase and zero otherwise.

The clinical validity score reflects the number of the highest clinical trials phase (from 1 to 4) on which the drug was ever tested for any pathology.

Method for prediction of pharmaceutical compounds

In this study, the focus was put on compounds with high pharmacological efficiency and low toxicity. For this purpose, comprehensive library of chemical compounds and drugs was subjected to a SAR/QSAR analysis. This library contains 13040 compounds along with their pre-calculated potential pharmacological activities of those substances, their possible side and toxic effects, as well as the possible mechanisms of action. All biological activities are expressed as probability values for a substance to exert this activity (*Pa*). We selected compounds that satisfied the following conditions:

- 1. Toxicity below a chosen toxicity threshold (defines as *Pa*, probability to be active as toxic substance).
- 2. For all predicted pharmacological effects that correspond to a set of user selected disease(s) *Pa* is greater than a chosen effect threshold.
- 3. There are at least 2 targets (corresponding to the predicted activity-mechanisms) with predicted *Pa* greater than a chosen target threshold.

The maximum *Pa* value for all toxicities corresponding to the given compound is selected as the "Toxicity score". The maximum *Pa* value for all activities corresponding to the selected diseases for the given compound is used as the "Disease activity score". "Target activity score" (T-score) is calculated as follows:

$$T\text{-}score(s) = \frac{|T|}{|T| + w(|AT| - |T|)} \sum_{m \in M(s)} \left( pa(m) \sum_{g \in G(m)} IAP(g) optWeight(g) \right),$$

where M(s) is the set of activity-mechanisms for the given structure (which passed the chosen threshold for activity-mechanisms P(a)); G(m) is the set of targets (converted to genes) that corresponds to the given activity-mechanism P(a) is the probability to be active of the activity-mechanism P(a) is the invariant accuracy of prediction for gene from P(a)0; optWeight(P(a)0) is the additional weight multiplier for gene. P(a)1 is set of all targets related to the compound intersected with input list, P(a)2 is number of elements in P(a)3. The set of all targets related to the compound and number of elements in it, P(a)3 is weight multiplier.

"Druggability score" (D-score) is calculated as follows:

$$D\text{-}score(g) = \mathit{IAP}(g) \sum_{s \in \mathit{S}(g)} \sum_{m \in \mathit{M}(s,g)} \mathit{pa}(m),$$

where S(g) is the set of structures for which target list contains given target, M(s,g) is the set of activity-mechanisms (for the given structure) that corresponds to the given gene, pa(m) is the probability to be active of the activity-mechanism (m), IAP(g) is the invariant accuracy of prediction for the given gene.

### Disclaimer

Decisions regarding care and treatment of patients should be fully made by attending doctors. The predicted chemical compounds listed in the report are given only for doctor's consideration and they cannot be treated as prescribed medication. It is the physician's responsibility to independently decide whether any, none or all of the predicted compounds can be used solely or in combination for patient treatment purposes, taking into account all applicable information regarding FDA prescribing recommendations for any therapeutic and the patient's condition, including, but not limited to, the patient's and family's medical history, physical examinations, information from various diagnostic tests, and patient preferences in accordance with the current standard of care. Whether or not a particular patient will benefit from a selected therapy is based on many factors and can vary significantly.

The compounds predicted to be active against the identified drug targets in the report are not guaranteed to be active against any particular patient's condition. GeneXplain GmbH does not give any assurances or guarantees regarding the treatment information and conclusions given in the report. There is no guarantee that any third party will provide a refund for any of the treatment decisions made based on these results. None of the listed compounds was checked by Genome Enhancer for adverse side-effects or even toxic effects.

The analysis report contains information about chemical drug compounds, clinical trials and disease biomarkers retrieved from the HumanPSD<sup>TM</sup> database of gene-disease assignments maintained and exclusively distributed worldwide by geneXplain GmbH. The information contained in this database is collected from scientific literature and public clinical trials resources. It is updated to the best of geneXplain's knowledge however we do not guarantee completeness and reliability of this information leaving the final checkup and consideration of the predicted therapies to the medical doctor.

The scientific analysis underlying the Genome Enhancer report employs a complex analysis pipeline which uses geneXplain's proprietary Upstream Analysis approach, integrated with TRANSFAC® and TRANSPATH® databases maintained and exclusively distributed worldwide by geneXplain GmbH. The pipeline and the databases are updated to the best of geneXplain's knowledge and belief, however, geneXplain GmbH shall not give a warranty as to the characteristics or to the content and any of the results produced by Genome Enhancer. Moreover, any warranty concerning the completeness, up-to-dateness, correctness and usability of Genome Enhancer information and results produced by it, shall be excluded.

The results produced by Genome Enhancer, including the analysis report, severely depend on the quality of input data used for the analysis. It is the responsibility of Genome Enhancer users to check the input data quality and parameters used for running the Genome Enhancer pipeline.

Note that the text given in the report is not unique and can be fully or partially repeated in other Genome Enhancer analysis reports, including reports of other users. This should be considered when publishing any results or excerpts from the report. This restriction refers only to the general description of analysis methods used for generating the report. All data and graphics referring to the concrete set of input data, including lists of mutated genes, differentially expressed genes/proteins/metabolites, functional classifications, identified transcription factors and master regulators, constructed molecular networks, lists of chemical compounds and reconstructed model of molecular mechanisms of the studied pathology are unique in respect to the used input data set and Genome Enhancer pipeline parameters used for the current run.
